Abstract

Array of absorbing pyramid cones are widely used in anechoic chambers to measure electromagnetic wave interference. Accuracy of measurements is related with absorbing performance of pyramidal structures on chamber walls. Absorbing performance of pyramidal structure depends on various parameters such as dielectric permittivity, magnetic permeability, material used for pyramids, physical dimensions of absorber etc. To determine effect of apex angle on absorption characteristics, absorbers which have different apex angles with same material are investigated. Reflectivity values are calculated. Both normal and oblique incidences of plane wave are analyzed. Results for different incidences angles and frequency bands are presented.

Keywords: Anechoic chamber; Electromagnetic wave interference; Apex angle; Absorption characteristic of pyramidal absorber.

1. Introduction

Pyramidal absorbers are widely used in anechoic chambers for the measurement of the electromagnetic wave interference. Absorption characteristic of them depends on their dimensions and dielectric properties in the given frequency band. Main purposes of researches are developing absorbers which have better low normal incidence reflection, low forward scattering and backscattering at wide incidence angle range, and reducing absorber height to use chamber space efficiently [1]. Pyramid geometry gave rise to multiple reflections in the direction of the pyramid apex. This facility was put to practical measurement use by the M. I. T. Radiation Laboratory [2]. Pyramidal absorber patented by Leland K. Neher in 1945 and he chose apex angle around 40° [3].

Since the size of individual pyramids are relatively large compared to a wavelength of incident plane wave, surfaces of pyramids reflect the incident wave. After reflection many times between adjacent pyramids surfaces, the wave is highly attenuated. Upon each reflection, a portion of the wave’s energy is absorbed by the lossy material of the pyramids. Amount of the absorbed energy is depends on reflection coefficient of the dielectric material (total reflection coefficient will be lower with more reflections). An extremely small portion of the incident wave can reach the metal back plate of the absorber array with multiple reflections [4]. Some portion of the incidence wave travels away from the pyramid array after several reflections. Reflection number of incident wave is depends on apex angle of the pyramids and incidence angle of the plane wave.
Here, we analyzed effect of apex angle value of a pyramid absorber on reflection coefficient. It can be explained easily by using reflection coefficient calculation for normal and oblique incidence at a plane lossy dielectric boundary of plane wave theory and Snell’s law of reflection. Since period of the array is relatively large compared with a wavelength, ray optics techniques can be used.

2. Theory

When the wavelength is small compared to significant dimensions of the objects, ray optics is applicable for incidence of electromagnetic wave to the objects [5].

Oblique incidence case of a uniform plane wave on a plane interface between two dielectric media (medium 2 is lossy for this case) can be used to explain reflection and transmission. Some portion of plane wave is reflected and other portion is transmitted. Reflection and refraction angles can be calculated easily by using Snell’s law of reflection and refraction. Reflection and transmission coefficient can also be calculated. This well-known subject is explained below by using Cheng’s study [6]. Let consider boundary between two media is \( \eta = 0 \), for perpendicular polarization case, the incidence electric and magnetic field intensity phasors in medium 1 are,

\[
E_i(x, z) = a_y E_{i0} e^{-j\beta_1(x \sin \theta_i + z \cos \theta_i)}
\]

\[
H_i(x, z) = \frac{E_{i0}}{\eta_1} (-a_x \cos \theta_i + a_z \sin \theta_i) e^{-j\beta_1(x \sin \theta_i + z \cos \theta_i)}
\]

The reflected electric and magnetic fields are,

\[
E_r(x, z) = a_y E_{r0} e^{-j\beta_2(x \sin \theta_t + z \cos \theta_t)}
\]

\[
H_r(x, z) = \frac{E_{r0}}{\eta_1} (-a_x \cos \theta_t + a_z \sin \theta_t) e^{-j\beta_2(x \sin \theta_t + z \cos \theta_t)}
\]

in medium 2 the transmitted electric and magnetic field intensity phasors are,

\[
E_t(x, z) = a_y E_{t0} e^{-\gamma_2(x \sin \theta_t + z \cos \theta_t)}
\]

\[
H_t(x, z) = \frac{E_{t0}}{\eta_2} (-a_x \cos \theta_t + a_z \sin \theta_t) e^{-\gamma_2(x \sin \theta_t + z \cos \theta_t)}
\]

from the requirements that the tangential components of \( E \) and \( H \) be continuous at the boundary \( z = 0 \). From \( E_{i0}(x, 0) + E_{r0}(x, 0) = E_{f0}(x, 0) \) and \( H_{i0}(x, 0) + H_{r0}(x, 0) = H_{f0}(x, 0) \) we have,

\[
E_{i0} e^{-j\beta_1 x \sin \theta_i} + E_{r0} e^{-j\beta_2 x \sin \theta_t} = E_{t0} e^{-\gamma_2 x \sin \theta_t}
\]

\[
\frac{1}{\eta_1} (-E_{i0} \cos \theta_i e^{-j\beta_1 x \sin \theta_i} + E_{r0} \cos \theta_t e^{-j\beta_2 x \sin \theta_t}) = -\frac{E_{t0}}{\eta_2} \cos \theta_i e^{-\gamma_2 x \sin \theta_t}
\]

from phase matching, we can write \( E_{i0} + E_{r0} = E_{t0} \) and \( \frac{1}{\eta_1} (E_{i0} - E_{r0}) \cos \theta_i = \frac{E_{t0}}{\eta_2} \cos \theta_t \). We have,

\[
\Gamma_2 = \frac{\eta_2 \cos \theta_i - \eta_1 \cos \theta_t}{\eta_2 \cos \theta_i + \eta_1 \cos \theta_t}
\]

for the parallel polarization case, the incidence electric and magnetic field intensity phasors in medium 1 are,

\[
E_i(x, z) = a_y E_{i0} e^{-j\beta_1(x \sin \theta_i + z \cos \theta_i)}
\]

\[
H_i(x, z) = a_y \frac{E_{i0}}{\eta_1 x} e^{-j\beta_1(x \sin \theta_i + z \cos \theta_i)}
\]
similarly to the perpendicular polarization case, from the requirements that the tangential components of $E$ and $H$ be continuous at the boundary $z=0$, reflection coefficient can be written as,

$$
\Gamma_i = \frac{\eta_2 \cos \theta_i - \eta_1 \cos \theta_i}{\eta_2 \cos \theta_i + \eta_1 \cos \theta_i}
$$

(12)
in general, total reflection coefficient will be,

$$
\Gamma = \Gamma_1 \Gamma_2 \Gamma_3 \ldots \Gamma_n
$$

(13)

where $\Gamma_i$ is $i$-th reflection coefficient, $i=1,2,3,\ldots,n$.

3. Simulation Results

In this section, several simulation results are presented for different pyramidal absorbers arrays which have different apex angles. They are analyzed by using well known commercial simulator, Ansoft’s HFFS software v12.1. HFFS utilizes a 3D full wave finite element method to compute the electrical behavior of high frequency components. Results are obtained for different apex angles of pyramidal arrays and different incidence angles of plane electromagnetic waves. %26 carbon loaded urethane is used as material which has relative dielectric permittivity $\varepsilon = 2.01 + 1.17\text{i}$ for 1000 MHz [4]. Magnetic permeability is $\mu = \mu_0 = 4\pi \times 10^{-7}\text{H/m}$ for the material. Base length of pyramids is $L=2\lambda$ which is suitable for ray optic approximation. Height of pyramids are $5.67\lambda$, $3.73\lambda$, $2.75\lambda$, $2.15\lambda$ for apex angles $20^\circ$, $30^\circ$, $40^\circ$, $50^\circ$ respectively. Table 1 shows reflection coefficients in decibel for 2 GHz.

| Apex angle | Incidence angle | $|R|\text{ (dB)}$ |
|------------|-----------------|-----------------|
| $20^\circ$ | $0^\circ$ | -48,1 | -44 |
| $30^\circ$ | $0^\circ$ | -42,6 | -43,2 |
| $40^\circ$ | $0^\circ$ | -32 | -32,8 |
| $50^\circ$ | $0^\circ$ | -25,3 | -25,5 |

4. Conclusion

Results show that $20^\circ$ apex angle has better absorption performance than others but it has $5.67\lambda$ height and this limits chamber space significantly. $30^\circ$ apex angle can provide optimal absorption performance based on percentage of height increment. Increment percentage is $35.64\%$ according to $30^\circ$ apex angle while $20^\circ$ apex angle’s increment percentage is $52.01\%$ and $40^\circ$ apex angle’s increment percentage is $27.91\%$. For example, for a 10m x 10m rectangular chamber with covered pyramidal absorber arrays, $20^\circ$ apex angle will occupy $16.29\%$ of total chamber area while $30^\circ$, $40^\circ$ and $50^\circ$ apex angles occupy $10.88\%$, $8.08\%$ and $6.35\%$ respectively.
