Exact Solution of Electromagnetic Scattering From a Dipole Antenna Located Inside a Multilayer Metamaterial Oblate Spheroidal Cavity

Yangqing Liu, Tadahiro Negishi, and Danilo Erricolo

Abstract — A new exact for a solution half oblate spheroidal cavity filled with double-negative and double-positive metamaterials and surrounded by perfect electric conductor walls with a circular opening is considered. The structure is illuminated by a dipole source, either electric or magnetic, located on the axis of symmetry and axially oriented. Analytical expressions and numerical examples are provided.

1. Introduction

Analytical solutions of electromagnetic scattering problems provide an exact mathematical description of the scattered field, which is important to learn the relationship between a given geometrical shape and the resulting scattered field. In this context, we refer to exact analytical solutions as expressions obtained from the solution of electromagnetic boundary value problems for which it is possible to obtain an exact mathematical representation, typically in the form of the sum of an infinite series involving an appropriate class of functions. In particular, the expansion coefficients of the series terms must be known a priori and not be the result of the evaluation of an infinite system of equations. The numerical computation of the sum of the series may benefit from the application of acceleration methods [1]. A brief literature survey finds that, in addition to the known exact solutions published in [2], the introduction of the isorefractive condition by Uslenghi [3, 4] allowed for the development of many new exact solutions. In particular, new geometries involving isorefractive materials are available for scattering from infinite bodies, such as shapes involving the 2D wedge [5–7], the elliptical cylinder [8–18], the paraboloid [19–21], and finite bodies, such as shapes involving spheroidal geometries [22–25].

The new geometry considered in this article consists of a perfect electric conductor (PEC) ground plane with a circular hole as shown in Fig. 1. Flush mounted underneath the hole, there is a PEC wall, shaped as a half-oblate spheroid, which determines a cavity. Inside the cavity there are two layers, one made of ordinary double-positive (DPS) material with positive dielectric permittivity and positive magnetic permeability and the other made of double-negative (DNG) metamaterial with negative dielectric permittivity and negative magnetic permeability. The interface between the two layers is an oblate spheroidal surface. The material outside the cavity and above the ground plane is DPS. The DPS and DNG materials are anti-isorefractive to each other. Preliminary results were presented in [26]. A related geometry with the cavity filled with isorefractive material was investigated in [22]. The cavity filled with DNG metamaterial was investigated in [27], while a cavity with two layers but with the dipole source located outside of the cavity was investigated in [25]. Exact analytic solutions for a dipole source located inside either one of the layers in the cavity, along the axis of symmetry of the structure and axially oriented, can be obtained. The solutions are expressed in terms of infinite series containing oblate spheroidal functions, according to the notation and properties given in [28] and [29]. The analytical solution is expressed in the phasor domain, where the time dependence $\text{e}^{i\omega t}$ is assumed and suppressed throughout. The relation between Cartesian coordinates $(x, y, z)$ and oblate spheroidal coordinates $(\eta, \zeta, \varphi)$ is

$$
\begin{align*}
x &= \frac{d}{2} \sqrt{(1 + \zeta^2)(1 - \eta^2)} \cos \varphi \\
y &= \frac{d}{2} \sqrt{(1 + \zeta^2)(1 - \eta^2)} \sin \varphi \\
z &= \frac{d}{2} \zeta 
\end{align*}
$$

with $0 \leq \zeta < \infty$, $-1 \leq \eta \leq 1$, and $0 \leq \varphi \leq 2\pi$.

2. Electric Dipole

For an electric dipole located along the $z$-axis at $(\zeta_0 < \zeta_1, \eta_0 = -1)$, corresponding to an incident electric Hertz vector $\pm \hat{z} \exp(i\mathbf{k}R)/(kR)$, the incident magnetic field is oriented in the $\varphi$-direction. The positive (negative) sign applies when the dipole is located inside a DPS (DNG) material [29]. In the absence of the cavity, the $\varphi$-component of the total field, that is, the sum of the incident field and the field reflected by the infinite metal plate at $z = 0$, is...
with unknown coefficients $d_i$ and $e_i$, and $Z_n$ is the impedance in the DNG layer. The unknown coefficients are obtained by enforcing the boundary conditions at $\xi = 0$, $\xi = \zeta_2$, and $\xi = \zeta_1$,

$$E_n,2|_{\xi=\zeta_1} = 0$$ \hspace{1cm} (6a) $$E_n,1|_{\xi=0} + E_n,1|_{\xi=\zeta_1} = 0$$ \hspace{1cm} (6b) $$H_{\varphi,1}|_{\xi=0} = H_{\varphi,2}|_{\xi=\zeta_1}$$ \hspace{1cm} (6c) $$E_n,1|_{\xi=\zeta_2} + E_n,2|_{\xi=\zeta_2} = 0$$ \hspace{1cm} (6d) $$H_{\varphi,1}|_{\xi=\zeta_2} = H_{\varphi,2}|_{\xi=\zeta_2}$$ \hspace{1cm} (6e)

where $H$ and $E$ are the total fields, $H = H' + H'' + H'$ at $z \leq 0$, and $H = H'$ at $z \geq 0$.

3. Magnetic Dipole

Similar to the electric dipole source case, a magnetic dipole along the $z$-axis at $(\zeta_0 < \zeta_1, \eta_0 = -1)$ corresponds to an incident magnetic Hertz vector $\pm \frac{1}{kR} \exp(ikR)/(kR)$ causing an incident electric field oriented in the $\varphi$-direction. In the absence of the cavity, the $\varphi$-component of the total field given by the sum of incident field and the field reflected by the infinite metal plate at $z = 0$ is

$$(E_{\varphi}' + E_{\varphi}')_D = \frac{-8k^2}{dZ_{\varphi} \omega \epsilon_\varphi \sqrt{\zeta_0^2 + 1}} \times \sum_{l=0}^{\infty} \frac{(-1)^l}{\rho_{1,2l+1}^{(1)}(-ic)N_{1,2l+1}^{(1)}(-ic)}$$

with an unknown coefficient $a_l$. In the DPS layer, the scattered magnetic field takes the form

$$H_{\varphi,DPS} = \frac{-4ik^2}{Z_{p}\sqrt{\zeta_0^2 + 1}} \times \sum_{l=0}^{\infty} \frac{(-1)^l}{\rho_{1,2l+1}^{(1)}(-ic)N_{1,2l+1}^{(1)}(-ic)}$$

$$(3)$$

with unknown coefficients $b_l$ and $c_l$. In the DNG layer, the scattered magnetic field due to the cavity takes the form of

$$H_{\varphi,DNG} = \frac{-4ik^2}{Z_{n}\sqrt{\zeta_0^2 + 1}} \times \sum_{l=0}^{\infty} \frac{(-1)^l}{\rho_{1,2l+1}^{(1)}(-ic)N_{1,2l+1}^{(1)}(-ic)}$$

$$(4)$$

with unknown coefficients $d_l$ and $e_l$, and $Z_n$ is the impedance in the DNG layer. The unknown coefficients are obtained by enforcing the boundary conditions at $\xi = 0$, $\xi = \zeta_2$, and $\xi = \zeta_1$.
\[ E_{\varphi,DNG}^i = \frac{-8k^2}{d\omega\epsilon_0} \sum_{n=0}^{\infty} \frac{(-1)^n S_{1,2l+1}(ic, -\eta)}{\sqrt{\epsilon_n^2 + 1}} \rho_{1,2l+1}(ic) N_{1,2l+1}(ic) \]
\[ \times \left[ d_{l}R_{1,2l+1}^{(1)}(ic, i\xi) + e_iR_{1,2l+1}^{(2)}(ic, i\xi) \right] \]

(10)

Again, to obtain the unknown coefficients, the following boundary conditions are enforced at \( \xi = 0, \xi = \xi_2 \), and \( \xi = \xi_1 \):

\[ E_{\varphi,1}\xi = 0 = 0 \]  \hspace{1cm} (11a)
\[ E_{\phi,2}\xi = 0 + E_{\phi,1}\xi = 0 \]  \hspace{1cm} (11b)
\[ H_{\eta,1}\xi = 0 = H_{\eta,2}\xi = 0 \]  \hspace{1cm} (11c)
\[ E_{\phi,1}\xi = \xi_2 + E_{\phi,2}\xi = \xi_2 \]  \hspace{1cm} (11d)
\[ H_{\eta,1}\xi = \xi_2 = H_{\eta,2}\xi = \xi_2 \]  \hspace{1cm} (11e)

and the total field \( E = E^i + E^r + E^s \) in the region \( z \leq 0 \) and \( E = E^d \) in the region \( z \geq 0 \).

4. Numerical Results

The numerical results for the total magnetic field by an electric dipole and for the total electric field by a magnetic dipole are obtained in MATLAB. Dipoles are placed at two locations inside the cavity: in layer 1 at \((\xi_0 = 0.25, \eta_0 = -1)\) (the green arrow in Figure 1) and in layer 2 at \((\xi_0 = 1.5, \eta_0 = -1)\) (the red arrow in Figure 1). The cavity material distribution has two cases: the DPS-DNG case with layer 1 DPS and layer 2 DNG and the DNG-DPS case with layer 1 DNG and layer 2 DPS. The oblate spheroidal cavity has boundaries at \( \xi_1 = 2 \) and \( \xi_2 = 0.5 \) when \( c = 1, d = 2, \) and \( \xi = \frac{\xi_{\text{PEC}}}{\xi_{\text{DPS}}} = 0.5 \). The magnitudes of the magnetic field due to an electric dipole, with incident electric Hertz vector \( \pm \hat{z} \exp(iKR)/(kR) \), at various locations and for different material combinations are given in Figures 3–6. The magnitudes of the electric field

Figure 2. Sample problem geometry: layer 1 is filled with DNG metamaterial and layer 2 with DPS material.

Figure 3. Magnitude of the total magnetic field due to an electric dipole in layer 1 for the DPS-DNG cavity.

Figure 4. Magnitude of the total magnetic field due to an electric dipole in layer 1 for the DNG-DPS cavity.

Figure 5. Magnitude of the total magnetic field by an electric dipole in layer 2 for the DPS-DNG cavity.
due to a magnetic dipole, with incident magnetic Hertz vector $\pm \hat{z} \exp(ikR)/(kR)$, at various locations and for different material combinations are given in Figures 7–10.

5. Conclusion

This new exact analytical solution for electric and magnetic dipoles radiating inside a two-layered cavity involving anti-isorefraction materials provides one additional benchmark for the validation of computational software [30].
